LAB 02 – Report

Tool Comparison

I used two OSINT tools (Sherlock and Maigret), to investigate the same username: primoz.mlakar

Sherlock located 3 profiles. Maigret, however, discovered 6 profiles with username primoz.mlakar and 146 account that includes primoz in username.

Sherlock

```
primoz@Student:~/Documents/personal_cybersecurity/maigret$ sherlock primoz.mlakar

Data Transparency

Sherlock presents a list of websites where the username was found.

Maigret delivers additional insights such as tags (e.g., gaming, networking, dating), possible

countries of activity, and structured profile data.

Unexpected Results

I found a lot of accounts with my name on sites that do not belong to me. It demonstrates how usernames can easily be reused by others or mistakenly linked to unrelated profiles, especially when the name is not completely unique.

Sensitive Information

No sensitive data were found. But the results show, how easily personal data could be exposed if privacy settings are not properly managed.

Protect Personal Data using:
- different usernames on platforms
- keep social media accounts private

Personal Reflection

This task show me, how much public data can be connected to a username.

After performing this analysis, I plan to create usernames without using my name and surname, update old accounts and remove unused accounts.

Ethical Considerations

I think that OSINT becomes ethically problematic when it is used for:
- stalking, harassment, doxxing, intimidation, or blackmail
- exposing private individuals who have no public-interest relevance;
- bypassing access controls or scraping restricted systems;
- creating dossiers on people for manipulation;
- targeting employees, family members, or vulnerable individuals;

The key issue is often aggregation risk. One public detail may be harmless. Ten linked public details can become dangerous.
